

ABSTRACT OF THE DISCLOSURE

A system and method for communicating between remote objects provided by service providers. The methods thereof are accessible as web services and client-sided local proxies in a computer network, in particular the Internet or LAN. A general service is installed in addition to existing services on the side of the service provider. The general service is used to connect one or several client service requests to the available services and to transmit one or several answer messages to the clients. An optimisation layer is implemented on the client side in addition to the other local proxies. The optimisation layer is configured to carry out client-sided optimisation and to combine groups of requests. Also, a general proxy is installed which is configured to carry out grouped service requests and to return answer messages to the optimisation layer.
